1 Introduction

2 Model

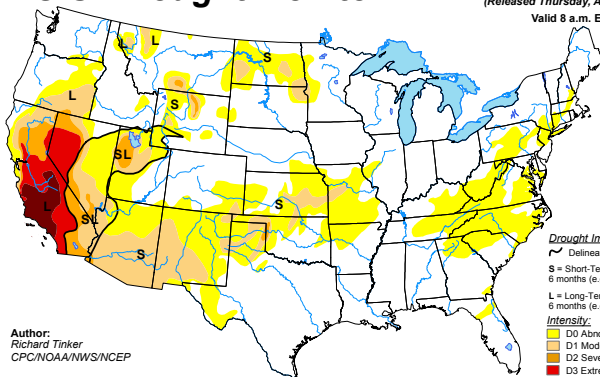

- First Stage
- Second Stage

3 DATA

- In April 2016 in the United States:
 - 14% of land was in drought and 34% was abnormally dry.
 - 84.3 million people live in drought-affected areas, and 17.5 million live in areas experiencing exceptional drought
- In California:
 - 90% of the state is in drought and more than 50% is in severe to exceptional drought.
 - 84.3 million people live in drought-affected areas, and 17.5 million live in areas experiencing exceptional drought

U.S. Drought Monitor

April 19, 2016
(Released Thursday, Apr. 21, 2016)
Valid 8 a.m. EDT

Author:
Richard Tinker
CPC/NOAA/NWS/NCEP

Drought Impact Types:

~ Delineates dominant impacts

S = Short-Term, typically less than 6 months (e.g. agriculture, grasslands)

L = Long-Term, typically greater than 6 months (e.g. hydrology, ecology)

Intensity:

- D0 Abnormally Dry
- D1 Moderate Drought
- D2 Severe Drought
- D3 Extreme Drought
- D4 Exceptional Drought

The Drought Monitor focuses on broad-scale conditions. Local conditions may vary. See accompanying text summary for forecast statements.

<http://droughtmonitor.unl.edu/>

- Climate change is likely to increase the length and severity
- Drought will effect all regions and populations at one time or another
- Resilience, not just risk of drought, will have far reaching implications for welfare changes from climate change.

First Stage Equation

$$y_{i,t} = \beta_i D_{i,t} + \alpha_i + \tau_i t + \gamma_{s,t} + \epsilon_{i,t} \quad (1)$$

Where:

- $D_{i,t}$ refers to the number of days in U.S. Drought Survey bins 2-4 in county i and year t
- α_i are county fixed effects controlling for time-invariant differences between counties
- τ_i is the coefficient on a county level linear time trend
- $\gamma_{s,t}$ are state-by-year fixed effects controlling for state level time trends common across all counties $i \in s$

First Stage Equation

- The state-by-year fixed effects will non-parametrically account for national trends in the outcome of interest as well as state-level trends
- The identifying variation in this model is within-county, annual deviations from the county time trend and from statewide annual average drought levels
- Standard errors will need to be corrected for serial correlation over space and time

Second Stage Equation

$$\beta_i = \rho_0 + \delta \mathbf{X}_i + \nu_i \quad (2)$$

Where:

- β_i come from Eq.(1) for a given outcome
- \mathbf{X}_i represents a vector of county characteristics such as urban/rural, proportion below age 5 or above age 65, home ownership, median cost of residential water bill
- δ is a vector of the associated coefficients for state level time trends common across all counties $i \in s$

Second Stage Equation

- This regression is cross-sectional and therefore not well identified from a causal perspective
- Model will illustrate how "drought resilience" (a low value of β_i) covaries with a set of common county socioeconomic characteristics
- We correct OLS standard errors by clustering over space

Blocks of Highlighted Text

Block 1

Lorem ipsum dolor sit amet, consectetur adipiscing elit. Integer lectus nisl, ultricies in feugiat rutrum, porttitor sit amet augue. Aliquam ut tortor mauris. Sed volutpat ante purus, quis accumsan dolor.
